General introduction

1.1. Context

The people who say they know about SQLIA, they knew and saw simple examples of what this type of attack can do, but they probably did know that SQLIA is one of the most devastating vulnerability that can infect a business. It can also steal a sensitive information, secure data, like a credit card number, personnel information. It can also lead to gain an administrative access to an application and manipulate it as they want.

1.2. Statement of the Problem:

SQL injection attacks pose a serious security threat to Web applications, they allow attackers to obtain unrestricted access to the databases underlying the applications and to the potentially sensitive information these databases contain. Although researchers and practitioners have proposed various methods to address the SQL injection problem, current approaches either fail to address the full scope of the problem or have limitations that prevent their use and adoption. Many researchers and practitioners are familiar with only a subset of the wide range of techniques available to attackers who are trying to take advantage of SQL injection vulnerabilities. As a consequence, many solutions proposed in the literature address only some of the issues related to SQL injection.

Because of that, developers go to implement SQL injection detection system (SQLIDS). The system monitors web-based applications and detects SQL injection attacks in real time. We report some preliminary experimental results over several SQL injection attacks that show that the proposed query-specific detection allows the system to perform focused analysis at negligible computational overhead without producing false positives or false negatives. Therefore, the new approach is very efficient in practice.

1.3. Objectives

1.3.1. General Objectives

The subject of this work is to develop a prototype tool that detects SQLIA using the information theoretic approach. The mean goal is to improve the detection of the new SQLIA's.

1.3.2. Specific Objectives

The intent of this work is to improve the implementation of Hossain Shahriar's approach that detects SQLIAs using the information theory. Our goals are:

- To improve the extraction and the detection of SQLIA to a dynamic way, without need to instrument the source code.
- To make this application work on several applications that was written in different programming language, which means answering this question:
 - How to extract the SQL query from the source code
 - How to manage the way this queries are written (format, space.....)
 - How to calculate the number of tokens in each query
 - How to calculate the entropy of every query

1.4. Methodology

Our implementation of this detection tool is divided in two phases: static and dynamic phases.

In the static one, we extract the queries from the dynamic pages which mean a problem of getting the dynamic pages, then, calculate the number of its tokens, which put's the problem of the way the query was written with. To resolve this problem, we made an SQL parser.

Then, we calculate the number of repetition of every single token, and the entropy. In the dynamic phase, which means when the query executes, we got the inputs of the user and we place them in the query and recalculate the entropy. Then we made a comparison between the first and the second value of the entropy, if it has been decreased or increased, then, we deal with the query that contains an injection.

1.5. Report Outline

This work divided in four chapters:

1.5.1. Chapter 01

The first chapter contains everything about SQLIAs; we present the seven types of injection attacks based on the mechanisms that used and the intents of the attacks, every type with an example and an explanation.

1.5.2. Chapter 02

In the second chapter, we summarize how to make a web application secure against SQLIA, using IDSs and its technologies, Then, we give the most common technologies developed to detect and prevent the SQLIA. And at the end, we list the approaches that used the theoretic information as a base of their security work.

1.5.3. Chapter 03

In the third chapter we define the information theoretic and its different concepts specially entropy which is the basic element of it, then, we define the mathematical formula to calculate it.

The second part of this chapter is about the application of “the detection of SQLIA’s based on information theoretic “approach

1.5.4. Chapter 04

In the fourth chapter we are going to explain more about the implementation of our tool using this approach. First of all, this java tool is implemented using eclipse, which is an integrated development environment for java. And we developed a dynamic website we called “security group”, as a security group that inform the users about its different products, as well as everything new in the security field. This web site is developed for the purpose of testing the SQLIA’s and the SQLI detector and we used the Dreamweaver for the design, and the Notepad for the code.

After that we define the different packages and programming languages, as well as the implementation of the web site and java application

1.5.2. Chapter 02

In the second chapter, we summarize how to make a web application secure against SQLIA, using IDSs and its technologies, Then, we give the most common technologies developed to detect and prevent the SQLIA. And at the end, we list the approaches that used the theoretic information as a base of their security work.

1.5.3. Chapter 03

In the third chapter we define the information theoretic and its different concepts specially entropy which is the basic element of it, then, we define the mathematical formula to calculate it.

The second part of this chapter is about the application of “the detection of SQLIA’s based on information theoretic “approach

1.5.4. Chapter 04

In the fourth chapter we are going to explain more about the implementation of our tool using this approach. First of all, this java tool is implemented using eclipse, which is an integrated development environment for java. And we developed a dynamic website we called “security group”, as a security group that inform the users about its different products, as well as everything new in the security field. This web site is developed for the purpose of testing the SQLIA’s and the SQLI detector and we used the Dreamweaver for the design, and the Notepad for the code.

After that we define the different packages and programming languages, as well as the implementation of the web site and java application

General Conclusion

Despite secure programming practices and many proactive countermeasures available, most of the web-based applications still suffer from SQLI vulnerabilities. Exploitations of SQLI vulnerabilities result in unwanted program behaviors and loss and leakage of confidential information of end users. Thus, SQLI mitigation needs to be considered seriously. This work detected SQLI attacks using an information-theoretic approach. We defined entropy as a measure to understand the complexity of the static query written by programmers. When a maliciously input successfully alters the static nature of the query, the complexity value changes. Thus, we rely on comparing the statically computed entropies with that of dynamically computed entropies. The deviation indicates the presence of SQLI in a query. The approach has been found to be effective for a set of vulnerable programs implemented in PHP. The approach allowed us to identify unknown SQLI attacks.

Our approach comprised two phases: In the static one, we explained how we extracted the queries and how we calculated the number of their tokens, the number of repetition of every single token, and the entropy. In the dynamic phase, which means when the query executes, we explained how we got the inputs of the user, placed them in the query and recalculated the entropy. Then we made comparison between the first and the second value of the entropy, whether it has been decreased or increased, then, the query contained an injection.

Actually, we did implement SQL injection detector based on this approach using the java language. We did test it in a web site that we did implement and the application has been effective on the detection of SQLIA's

Our future work includes testing the application on several web applications. We also plan to apply our developed to detect other web-based applications written in other programming languages.

ABSTRACT

SQL Injection (SQLI) is a widespread vulnerability commonly found in web-based programs. Exploitations of SQL injection vulnerabilities lead to harmful consequences such as authentication bypassing and leakage of sensitive personal information. Therefore, SQLI needs to be mitigated to protect end users. In this work, we present an approach to detect SQLI attacks based on information theory. We compute the entropy of each query present in a program accessed before program deployment. During the program execution time, when an SQL query is invoked, we compute the entropy again to identify any change in the entropy measure for that query. The approach then relies on the assumption that dynamic queries with attack inputs result in increased or decreased level of entropy. In contrast, a dynamic query with benign inputs does not result in any change of entropy value.

Keywords: SQL injection, software vulnerability, information theory, entropy.

Résumé

L'Injection SQL (SQLI) est une vulnérabilité répandue trouvée couramment dans les programmes basés sur le Web. Les exploitations de vulnérabilités d'injection SQL mènent à des conséquences néfastes telles que l'authentification contournement et la fuite d'informations personnelles sensibles. Par conséquent, SQLI doit être atténuée afin de protéger les utilisateurs finaux. Dans ce travail, nous présentons une approche pour détecter les attaques de SQLI basées sur la théorie de l'information. Nous calculons l'entropie de chaque requête présente dans un programme consultée avant le déploiement du programme. Au cours du programme le temps d'exécution, lors d'une requête SQL est invoqué, nous calculons à nouveau l'entropie pour identifier tout changement dans la mesure de l'entropie pour cette requête. L'approche repose donc sur l'hypothèse que les requêtes dynamiques avec des entrées d'attaque entraînent une augmentation ou une diminution du niveau de l'entropie. En revanche, une requête dynamique avec des entrées bénignes ne conduit pas à un changement de la valeur de l'entropie.

Mots-clés: injection SQL, vulnérabilité du logiciel, théorie de l'information, l'entropie.

ملخص

الـ SQL Injection (SQLI) هو عبارة عن واحدة من أكثر الثغرات انتشارا والتي نجدها في برامج Web ، استغلال هذه الثغرات يؤدي إلى عواقب وخيمة مثل تجاوز المصادقة و تسريب المعلومات الشخصية الحساسة. لذلك يجب تعديل SQLI لحماية المستخدمين النهائيين. في هذا العمل نقدم طريقة لكشف الـ SQLIA's بالاعتماد على information theory ، نقوم بحساب الـ entropy الخاص بكل query يظهر في التطبيق ، وحين استدعاه نقوم بحساب الـ entropy مرة أخرى لتحديد التغير في القيمة، ذلك على حساب أن إدخال المعلومات التي تحتوي على SQLI سيتسبب في تزايد أو تناقص الـ entropy بنسبة كبيرة، و إدخال المعلومات الصحيحة لن يتسبب في أي تغير.

الكلمات المفتاحية: SQL injection ، entropy ، Web ، SQLIA ، information theory ، query .
